

	N=20	
	Percentage of success in 100 runs	Elapsed time to complete experiment (secs)
a) Basic Hill Climbing	2%	0.10
b) Random Restart with k=10	23%	1.12
b) Random Restart with k=100	92%	4.24
c) Stochastic Hill climbing	1%	0.18
d) Enter your short summary	Random-restart hill climbing with k=100 achieved by far the highest success rate (92%) but also had the largest running time per experiment. Basic and stochastic hill climbing were very fast but almost always got stuck in local optima, while random restart with k=10 provided a moderate trade off between success rate and time.
